The Optimal Solution

Richard Vaughan D17125335

Dublin School of Architecture

1) Abstract

Kildress House is a recently completed, airconditioned office building in Dublin city centre.

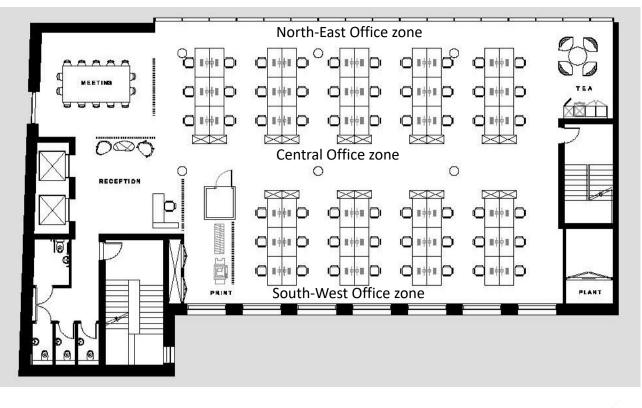

Using Design Builder software, a number of dynamic simulation studies were completed on the building to show that a passive cooling solution can be feasible alternative to airconditioning.

This can result in lower energy consumption

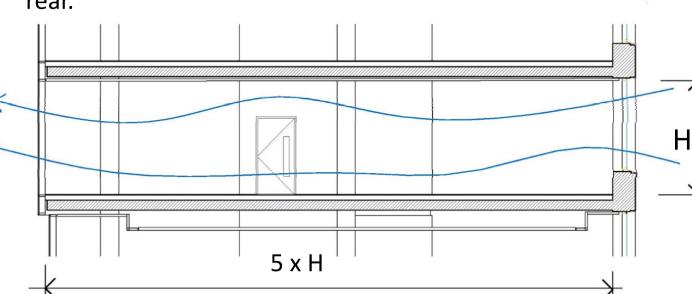

while still achieving thermal comfort levels and maintaining suitable levels of daylighting within the open plan office areas.

This study focuses on simple alterations to the façade such as shading, natural ventilation and high performance glazing to achieve a passive cooling solution.

An optimal solution was then established that met the required parameters and had the lowest energy use.

The building has an open plan office layout with full height glazing to the front and large windows at the rear.

A building depth of 15.5m means that it is still possible to achieve a natural ventilation solution.

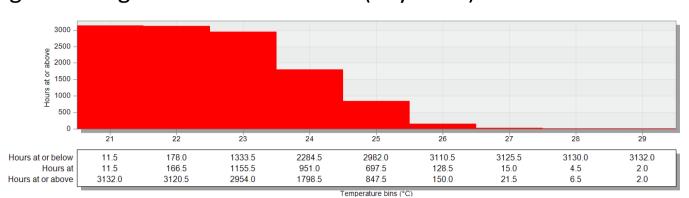

2) Preliminary study

One floor of the building and surrounding context was modelled in Design Builder without air-conditioning to

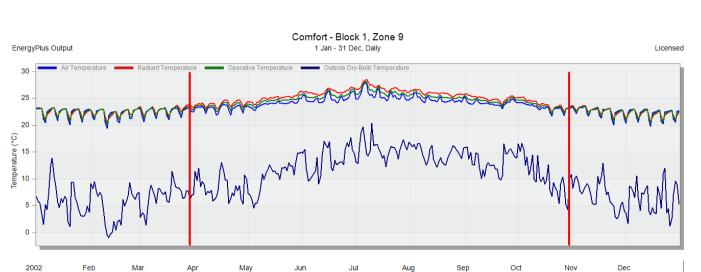

Internal Gains + solar - Block 1, Zone 6

Annual internal gains in the north-east office zone show solar gain during the summer months (in yellow)

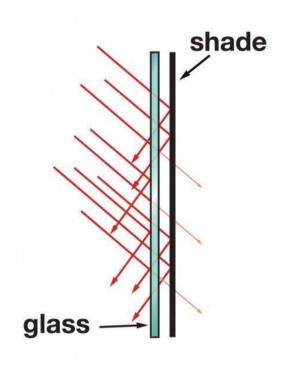

Thermal comfort levels in the central office zone show that 27% of occupied hours are over 25°

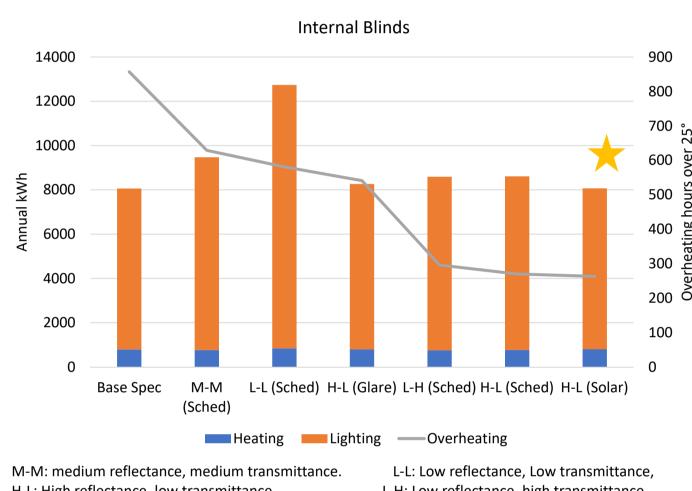

Annual temperature in the central office zone peaks at 29°

3) Detailed Study

Internal blinds

- Internal blinds reduce glare and provide privacy
- Have an impact on energy for lighting and thermal comfort.
- High reflectance, low transmittance blinds are the most effective at reducing overheating
- Blinds are most effective if operated based on solar radiation.

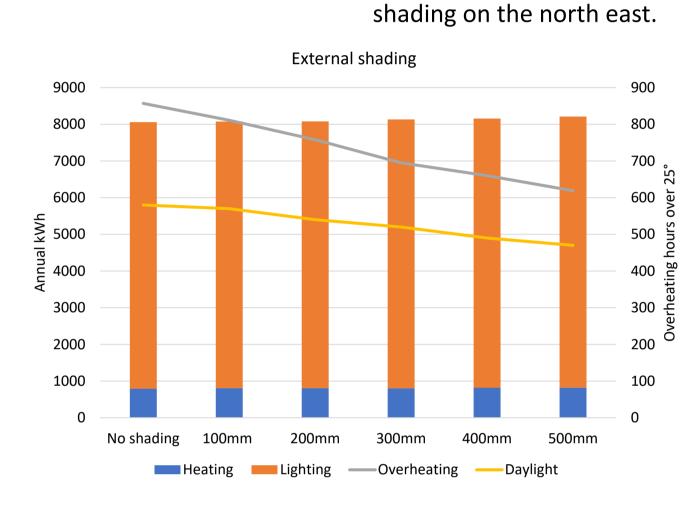

H-L: High reflectance, low transmittance, L-H: Low reflectance, high transmittance

External Shading

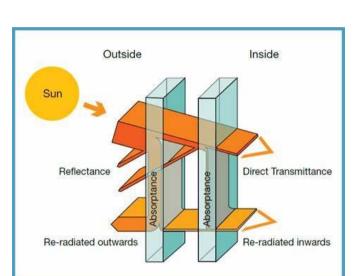

- Shading reduces internal daylight levels
- Improves thermal comfort conditions
- Increases energy use for both heating and lighting
- Horizontal shading was measured on the south-west elevation and vertical

Natural Ventilation

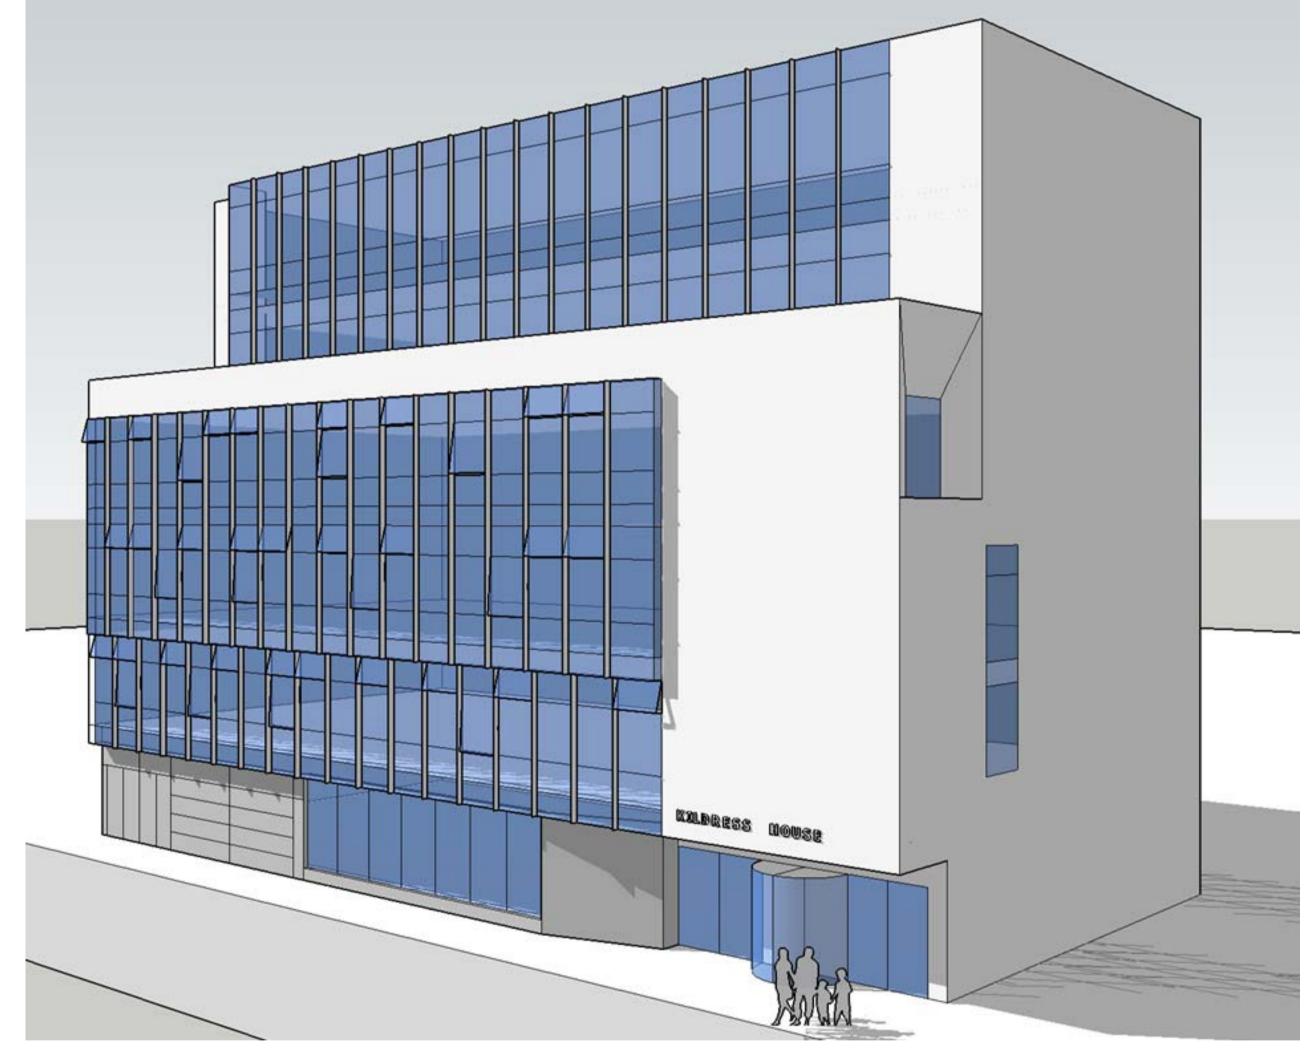

By increasing the open area of the windows and therefore the amount of natural ventilation:

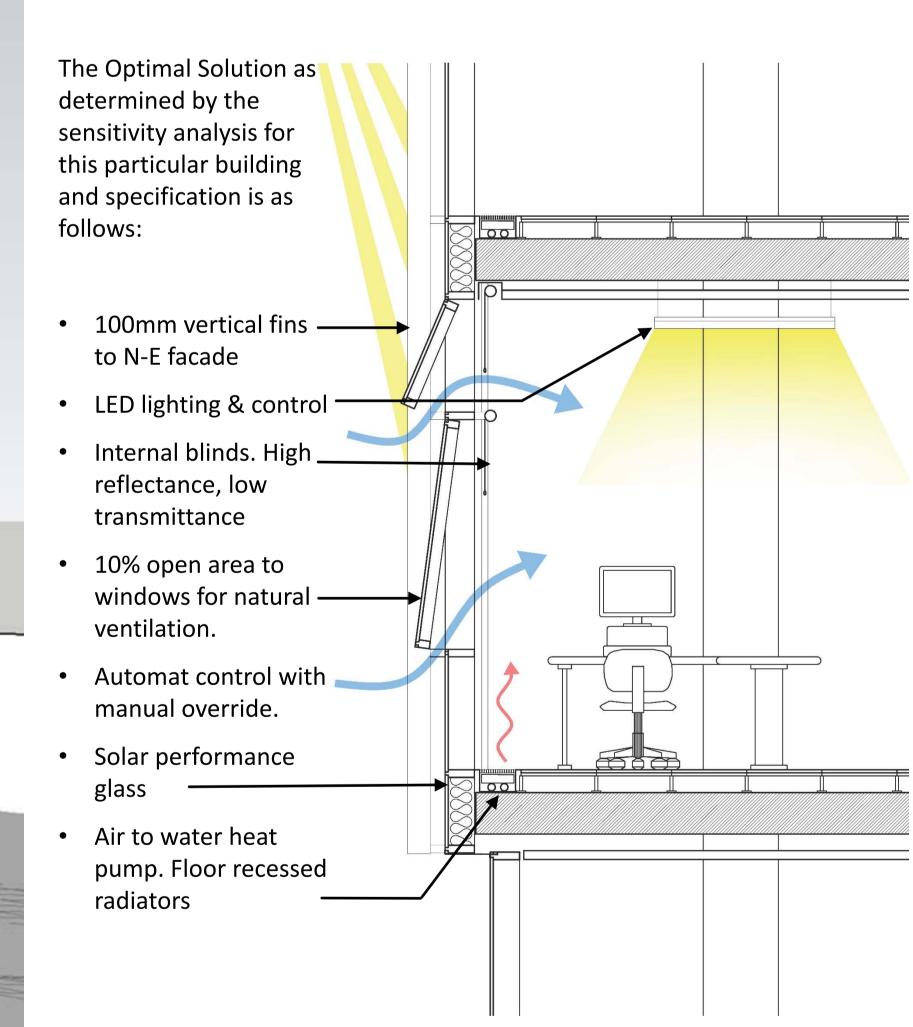

- Results in a large reduction in overheating hours due to passive cooling.
- The energy required or heating increases due to a certain amount of overcooling that is often a result of the external weather conditions.
- There is no impact on the daylighting or the energy for lighting

4) The Optimal Solution

| | Shading | Nat Vent | Glass | Thermal Comfort | Daylight Factor | Energy | |
|----|---------|----------|-----------|-----------------|-----------------|--------|--|
| 1 | 100mm | 10% | 0.26/0.51 | 28.5 | 3.2 | 8737 | |
